

NAME

system-config-printer-applet – print job manager

SYNOPSIS

system-config-printer-applet [--help] [--version] [--debug]

DESCRIPTION

system-config-printer-applet is a print job manager for CUPS. Normally it will display a printer icon in the notification area, greyed out when there are no print jobs for the current user. Clicking on the icon displays a simple print job manager for cancelling or reprinting jobs.

To save memory, the applet waits first of all until the user has printed a job before putting the icon in the notification area. To invoke the print job manager before a job has been printed, run the applet with the **--no-tray-icon** option: a desktop file is provided for this, so that it should appear in the system menu.

As well as displaying a printer icon in the notification area, the applet also provides a D-BUS server for the com.redhat.PrintDriverSelection interface, to help configure a new printer when it is plugged in.

OPTIONS**--help**

Display a short usage message.

--version

Display the version of the applet.

--debug

Show debugging information.
