

**NAME**

searchable-scrollback – incremental scrollbar search (enabled by default)

**DESCRIPTION**

Adds regex search functionality to the scrollbar buffer, triggered by the `searchable-scrollback:start` action (bound to `M-s` by default). While in search mode, normal terminal input/output is suspended and a regex is displayed at the bottom of the screen.

Inputting characters appends them to the regex and continues incremental search. `BackSpace` removes a character from the regex, `Up` and `Down` search upwards/downwards in the scrollbar buffer, `End` jumps to the bottom. `Escape` leaves search mode and returns to the point where search was started, while `Enter` or `Return` stay at the current position and additionally stores the first match in the current line into the primary selection if the `Shift` modifier is active.

The regex defaults to “`(?i)`”, resulting in a case-insensitive search. To get a case-sensitive search you can delete this prefix using `BackSpace` or simply use an uppercase character which removes the “`(?i)`” prefix.

See `perlre` for more info about perl regular expression syntax.
