

NAME

`atexit` – register a function to be called at normal process termination

SYNOPSIS

```
#include <stdlib.h>
```

```
int atexit(void (*function)(void));
```

DESCRIPTION

The `atexit()` function registers the given *function* to be called at normal process termination, either via `exit(3)` or via return from the program's `main()`. Functions so registered are called in the reverse order of their registration; no arguments are passed.

The same function may be registered multiple times: it is called once for each registration.

POSIX.1 requires that an implementation allow at least **ATEXIT_MAX** (32) such functions to be registered. The actual limit supported by an implementation can be obtained using `sysconf(3)`.

When a child process is created via `fork(2)`, it inherits copies of its parent's registrations. Upon a successful call to one of the `exec(3)` functions, all registrations are removed.

RETURN VALUE

The `atexit()` function returns the value 0 if successful; otherwise it returns a nonzero value.

ATTRIBUTES

For an explanation of the terms used in this section, see `attributes(7)`.

Interface	Attribute	Value
<code>atexit()</code>	Thread safety	MT-Safe

CONFORMING TO

POSIX.1-2001, POSIX.1-2008, C89, C99, SVr4, 4.3BSD.

NOTES

Functions registered using `atexit()` (and `on_exit(3)`) are not called if a process terminates abnormally because of the delivery of a signal.

If one of the registered functions calls `_exit(2)`, then any remaining functions are not invoked, and the other process termination steps performed by `exit(3)` are not performed.

POSIX.1 says that the result of calling `exit(3)` more than once (i.e., calling `exit(3)` within a function registered using `atexit()`) is undefined. On some systems (but not Linux), this can result in an infinite recursion; portable programs should not invoke `exit(3)` inside a function registered using `atexit()`.

The `atexit()` and `on_exit(3)` functions register functions on the same list: at normal process termination, the registered functions are invoked in reverse order of their registration by these two functions.

According to POSIX.1, the result is undefined if `longjmp(3)` is used to terminate execution of one of the functions registered using `atexit()`.

Linux notes

Since glibc 2.2.3, `atexit()` (and `on_exit(3)`) can be used within a shared library to establish functions that are called when the shared library is unloaded.

EXAMPLE

```
#include <stdio.h>
#include <stdlib.h>
#include <unistd.h>

void
bye(void)
{
    printf("That was all, folks\n");
}
```

```
    }

    int
    main(void)
    {
        long a;
        int i;

        a = sysconf(_SC_ATEXIT_MAX);
        printf("ATEXIT_MAX = %ld\n", a);

        i = atexit(bye);
        if (i != 0) {
            fprintf(stderr, "cannot set exit function\n");
            exit(EXIT_FAILURE);
        }

        exit(EXIT_SUCCESS);
    }
```
