NAME

Locale::gettext - message handling functions

SYNOPSIS

DESCRIPTION

The gettext module permits access from perl to the **gettext()** family of functions for retrieving message strings from databases constructed to internationalize software.

```
$d = Locale::gettext->domain(DOMAIN)
$d = Locale::gettext->domain_raw(DOMAIN)
```

Creates a new object for retrieving strings in the domain **DOMAIN** and returns it. domain requests that strings be returned as Perl strings (possibly with wide characters) if possible while domain_raw requests that octet strings directly from functions like dgettext().

\$d->get(MSGID)

Calls dgettext () to return the translated string for the given MSGID.

```
$d->cget(MSGID, CATEGORY)
```

Calls dcgettext () to return the translated string for the given MSGID in the given CATEGORY.

```
$d->nget(MSGID, MSGID_PLURAL, N)
```

Calls dngettext() to return the translated string for the given $MSGID_PLURAL$ depending on N.

```
$d->ncget(MSGID, MSGID_PLURAL, N, CATEGORY)
```

Calls dngettext() to return the translated string for the given $MSGID_PLURAL$ depending on N in the given CATEGORY.

```
$d->dir([NEWDIR])
```

If **NEWDIR** is given, calls bindtextdomain to set the name of the directory where messages for the domain represented by \$d are found. Returns the (possibly changed) current directory name.

```
$d->codeset([NEWCODE])
```

For instances created with Locale::gettext->domain_raw, manuiplates the character set of the returned strings. If **NEWCODE** is given, calls bind_textdomain_codeset to set the character encoding in which messages for the domain represented by \$d are returned. Returns the (possibly changed) current encoding name.

<code>gettext()</code>, <code>dgettext()</code>, and <code>dcgettext()</code> attempt to retrieve a string matching their msgid parameter within the context of the current locale. <code>dcgettext()</code> takes the message's category and the text domain as parameters while <code>dgettext()</code> defaults to the <code>LC_MESSAGES</code> category and <code>gettext()</code> defaults to <code>LC_MESSAGES</code> and uses the current text domain. If the string is not found in the database, then <code>msgid</code> is returned.

ngettext(), **dngettext()**, and **dcngettext()** function similarly but implement differentiation of messages between singular and plural. See the documentation for the corresponding C functions for details.

textdomain() sets the current text domain and returns the previously active domain.

bindtextdomain(domain, dirname) instructs the retrieval functions to look for the databases belonging to domain domain in the directory dirname

bind_textdomain_codeset(domain, codeset) instructs the retrieval functions to translate the returned messages to the character encoding given by **codeset** if the encoding of the message catalog is known.

NOTES

Not all platforms provide all of the functions. Functions that are not available in the underlying C library will not be available in Perl either.

Perl programs should use the object interface. In addition to being able to return native Perl wide character strings, bind_textdomain_codeset will be emulated if the C library does not provide it.

VERSION

1.07.
