NAME

strfromd, strfromf, strfroml - convert a floating-point value into a string

SYNOPSIS

DESCRIPTION

These functions convert a floating-point value, fp, into a string of characters, str, with a configurable format string. At most n characters are stored into str.

The terminating null character ($\0$) is written if and only if n is sufficiently large, otherwise the written string is truncated at n characters.

The **strfromd**(), **strfromf**(), and **strfroml**() functions are equivalent to

```
snprintf(str, n, format, fp);
except for the format string.
```

Format of the format string

The *format* string must start with the character '%'. This is followed by an optional precision which starts with the period character (.), followed by an optional decimal integer. If no integer is specified after the period character, a precision of zero is used. Finally, the format string should have one of the conversion specifiers **a**, **A**, **e**, **E**, **f**, **F**, **g**, or **G**.

The conversion specifier is applied based on the floating-point type indicated by the function suffix. Therefore, unlike **snprintf**(), the format string does not have a length modifier character. See **snprintf**(3) for a detailed description of these conversion specifiers.

The implementation conforms to the C99 standard on conversion of NaN and infinity values:

If fp is a NaN, +NaN, or -NaN, and \mathbf{f} (or \mathbf{a} , \mathbf{e} , \mathbf{g}) is the conversion specifier, the conversion is to "nan", "nan", or "-nan", respectively. If \mathbf{F} (or \mathbf{A} , \mathbf{E} , \mathbf{G}) is the conversion specifier, the conversion is to "NAN" or "-NAN".

Likewise if fp is infinity, it is converted to [-]inf or [-]INF.

A malformed *format* string results in undefined behavior.

RETURN VALUE

The strfromd(), strfromf(), and strfroml() functions return the number of characters that would have been written in str if n had enough space, not counting the terminating null character. Thus, a return value of n or greater means that the output was truncated.

VERSIONS

The **strfromd()**, **strfromf()**, and **strfroml()** functions are available in glibc since version 2.25.

ATTRIBUTES

For an explanation of the terms used in this section, see **attributes**(7) and the **POSIX Safety Concepts** section in GNU C Library manual.

Interface	Attribute	Value
strfromd(),	Thread safety	MT-Safe locale
strfromf(),	Asynchronous signal safety	AS-Unsafe heap
strfroml()	Asynchronous cancellation safety	AC-Unsafe mem

Note: these attributes are preliminary.

CONFORMING TO

C99, ISO/IEC TS 18661-1.

NOTES

The **strfromd**(), **strfromf**(), and **strfroml**() functions take account of the **LC_NUMERIC** category of the current locale.

EXAMPLES

To convert the value 12.1 as a float type to a string using decimal notation, resulting in "12.100000":

```
#define __STDC_WANT_IEC_60559_BFP_EXT__
#include <stdlib.h>
int ssize = 10;
char s[ssize];
strfromf(s, ssize, "%f", 12.1);
```

To convert the value 12.3456 as a float type to a string using decimal notation with two digits of precision, resulting in "12.35":

```
#define __STDC_WANT_IEC_60559_BFP_EXT__
#include <stdlib.h>
int ssize = 10;
char s[ssize];
strfromf(s, ssize, "%.2f", 12.3456);
```

To convert the value 12.345e19 as a double type to a string using scientific notation with zero digits of precision, resulting in "1E+20":

```
#define __STDC_WANT_IEC_60559_BFP_EXT__
#include <stdlib.h>
int ssize = 10;
char s[ssize];
strfromd(s, ssize, "%.E", 12.345e19);
```
