NAME

flower - flow based traffic control filter

SYNOPSIS

tc filter ... flower [MATCH_LIST] [action ACTION_SPEC] [classid CLASSID] [hw_tc TCID]

 $MATCH_LIST := [MATCH_LIST]MATCH$

DESCRIPTION

The **flower** filter matches flows to the set of keys specified and assigns an arbitrarily chosen class ID to packets belonging to them. Additionally (or alternatively) an action from the generic action framework may be called.

OPTIONS

action ACTION_SPEC

Apply an action from the generic actions framework on matching packets.

classid CLASSID

Specify a class to pass matching packets on to. CLASSID is in the form X:Y, while X and Y are interpreted as numbers in hexadecimal format.

hw_tc TCID

Specify a hardware traffic class to pass matching packets on to. TCID is in the range 0 through 15.

indev ifname

Match on incoming interface name. Obviously this makes sense only for forwarded flows. *ifname* is the name of an interface which must exist at the time of **tc** invocation.

verbose

Enable verbose logging, including offloading errors when not using **skip_sw** flag.

skip_sw

Do not process filter by software. If hardware has no offload support for this filter, or TC offload is not enabled for the interface, operation will fail.

skip_hw

Do not process filter by hardware.

dst_mac MASKED_LLADDR src_mac MASKED_LLADDR

Match on source or destination MAC address. A mask may be optionally provided to limit the bits of the address which are matched. A mask is provided by following the address with a slash and then the mask. It may be provided in LLADDR format, in which case it is a bitwise mask, or as a number of high bits to match. If the mask is missing then a match on all bits is assumed.

vlan_id VID

Match on vlan tag id. VID is an unsigned 12bit value in decimal format.

vlan_prio PRIORITY

Match on vlan tag priority. PRIORITY is an unsigned 3bit value in decimal format.

vlan ethtype VLAN ETH TYPE

Match on layer three protocol. *VLAN_ETH_TYPE* may be either **ipv4**, **ipv6** or an unsigned 16bit value in hexadecimal format. To match on QinQ packet, it must be 802.1Q or 802.1AD.

cvlan_id VID

Match on QinQ inner vlan tag id. VID is an unsigned 12bit value in decimal format.

cvlan_prio PRIORITY

Match on QinQ inner vlan tag priority. PRIORITY is an unsigned 3bit value in decimal format.

cvlan_ethtype VLAN_ETH_TYPE

Match on QinQ layer three protocol. *VLAN_ETH_TYPE* may be either **ipv4**, **ipv6** or an unsigned 16bit value in hexadecimal format.

mpls_label LABEL

Match the label id in the outermost MPLS label stack entry. *LABEL* is an unsigned 20 bit value in decimal format.

mpls_tc TC

Match on the MPLS TC field, which is typically used for packet priority, in the outermost MPLS label stack entry. TC is an unsigned 3 bit value in decimal format.

mpls bos BOS

Match on the MPLS Bottom Of Stack field in the outermost MPLS label stack entry. BOS is a 1 bit value in decimal format.

mpls_ttl TTL

Match on the MPLS Time To Live field in the outermost MPLS label stack entry. *TTL* is an unsigned 8 bit value in decimal format.

ip_proto IP_PROTO

Match on layer four protocol. *IP_PROTO* may be **tcp**, **udp**, **sctp**, **icmp**, **icmpv6** or an unsigned 8bit value in hexadecimal format.

ip_tos MASKED_IP_TOS

Match on ipv4 TOS or ipv6 traffic-class - eight bits in hexadecimal format. A mask may be optionally provided to limit the bits which are matched. A mask is provided by following the value with a slash and then the mask. If the mask is missing then a match on all bits is assumed.

ip ttl MASKED IP TTL

Match on ipv4 TTL or ipv6 hop-limit - eight bits value in decimal or hexadecimal format. A mask may be optionally provided to limit the bits which are matched. Same logic is used for the mask as with matching on ip_tos.

dst_ip PREFIX

src_ip PREFIX

Match on source or destination IP address. *PREFIX* must be a valid IPv4 or IPv6 address, depending on the **protocol** option to tc filter, optionally followed by a slash and the prefix length. If the prefix is missing, **tc** assumes a full-length host match.

dst_port { NUMBER | MIN_VALUE-MAX_VALUE } src port { NUMBER | MIN VALUE-MAX VALUE }

Match on layer 4 protocol source or destination port number. Alternatively, the mininum and maximum values can be specified to match on a range of layer 4 protocol source or destination port numbers. Only available for **ip_proto** values **udp**, **tcp** and **sctp** which have to be specified in beforehand.

tcp_flags MASKED_TCP_FLAGS

Match on TCP flags represented as 12bit bitfield in in hexadecimal format. A mask may be optionally provided to limit the bits which are matched. A mask is provided by following the value with a slash and then the mask. If the mask is missing then a match on all bits is assumed.

type MASKED_TYPE code MASKED_CODE

Match on ICMP type or code. A mask may be optionally provided to limit the bits of the address which are matched. A mask is provided by following the address with a slash and then the mask. The mask must be as a number which represents a bitwise mask If the mask is missing then a match on all bits is assumed. Only available for **ip_proto** values **icmp** and **icmpv6** which have to be specified in beforehand.

```
arp_tip IPV4_PREFIX
arp_sip IPV4_PREFIX
```

Match on ARP or RARP sender or target IP address. *IPV4_PREFIX* must be a valid IPv4 address optionally followed by a slash and the prefix length. If the prefix is missing, **tc** assumes a full-length host match.

arp_op ARP_OP

Match on ARP or RARP operation. *ARP_OP* may be **request**, **reply** or an integer value 0, 1 or 2. A mask may be optionally provided to limit the bits of the operation which are matched. A mask is provided by following the address with a slash and then the mask. It may be provided as an unsigned 8 bit value representing a bitwise mask. If the mask is missing then a match on all bits is assumed.

```
arp_sha MASKED_LLADDR arp_tha MASKED_LLADDR
```

Match on ARP or RARP sender or target MAC address. A mask may be optionally provided to limit the bits of the address which are matched. A mask is provided by following the address with a slash and then the mask. It may be provided in LLADDR format, in which case it is a bitwise mask, or as a number of high bits to match. If the mask is missing then a match on all bits is assumed.

```
enc_key_id NUMBER
enc_dst_ip PREFIX
enc_src_ip PREFIX
enc_dst_port NUMBER
enc_tos NUMBER
enc_ttl NUMBER
geneve_opts OPTIONS
```

Match on IP tunnel metadata. Key id *NUMBER* is a 32 bit tunnel key id (e.g. VNI for VXLAN tunnel). *PREFIX* must be a valid IPv4 or IPv6 address optionally followed by a slash and the prefix length. If the prefix is missing, **tc** assumes a full-length host match. Dst port *NUMBER* is a 16 bit UDP dst port. Tos *NUMBER* is an 8 bit tos (dscp+ecn) value, ttl *NUMBER* is an 8 bit time-to-live value. geneve_opts *OPTIONS* must be a valid list of comma-separated geneve options where each option consists of a key optionally followed by a slash and corresponding mask. If the masks is missing, **tc** assumes a full-length match. The options can be described in the form CLASS:TYPE:DATA/CLASS_MASK:TYPE_MASK:DATA_MASK, where CLASS is represented as a 16bit hexadecimal value, TYPE as an 8bit hexadecimal value and DATA as a variable length hexadecimal value.

ip_flags IP_FLAGS

IP_FLAGS may be either **frag**, **nofrag**, **firstfrag** or **nofirstfrag** where frag and nofrag could be used to match on fragmented packets or not, respectively. firstfrag and nofirstfrag can be used to further distinguish fragmented packet. firstfrag can be used to indicate the first fragmented packet. nofirstfrag can be used to indicates subsequent fragmented packets or non-fragmented packets.

NOTES

As stated above where applicable, matches of a certain layer implicitly depend on the matches of the next lower layer. Precisely, layer one and two matches (**indev**, **dst_mac** and **src_mac**) have no dependency, MPLS and layer three matches (**mpls_label**, **mpls_tc**, **mpls_bos**, **mpls_ttl**, **ip_proto**, **dst_ip**, **src_ip**, **arp_tip**, **arp_sip**, **arp_op**, **arp_tha**, **arp_sha** and **ip_flags**) depend on the **protocol** option of tc filter, layer four port matches (**dst_port** and **src_port**) depend on **ip_proto** being set to **tcp**, **udp** or **sctp**, and finally ICMP matches (**code** and **type**) depend on **ip_proto** being set to **icmp** or **icmpv6**.

There can be only used one mask per one prio. If user needs to specify different mask, he has to use different prio.
