## **NAME**

systemd-machine-id-setup - Initialize the machine ID in /etc/machine-id

#### **SYNOPSIS**

systemd-machine-id-setup

## DESCRIPTION

**systemd–machine–id–setup** may be used by system installer tools to initialize the machine ID stored in /etc/machine–id at install time, with a provisioned or randomly generated ID. See **machine-id**(5) for more information about this file.

If the tool is invoked without the **—commit** switch, /etc/machine—id is initialized with a valid, new machined ID if it is missing or empty. The new machine ID will be acquired in the following fashion:

- 1. If a valid D–Bus machine ID is already configured for the system, the D–Bus machine ID is copied and used to initialize the machine ID in /etc/machine-id.
- 2. If run inside a KVM virtual machine and a UUID is configured (via the **–uuid** option), this UUID is used to initialize the machine ID. The caller must ensure that the UUID passed is sufficiently unique and is different for every booted instance of the VM.
- 3. Similarly, if run inside a Linux container environment and a UUID is configured for the container, this is used to initialize the machine ID. For details, see the documentation of the **Container Interface**<sup>[1]</sup>.
- 4. Otherwise, a new ID is randomly generated.

The **—commit** switch may be used to commit a transient machined ID to disk, making it persistent. For details, see below.

Use **systemd-firstboot**(1) to initialize the machine ID on mounted (but not booted) system images.

#### **OPTIONS**

The following options are understood:

#### **--root**=root

Takes a directory path as argument. All paths operated will be prefixed with the given alternate *root* path, including the path for /etc/machine-id itself.

# --commit

Commit a transient machine ID to disk. This command may be used to convert a transient machine ID into a persistent one. A transient machine ID file is one that was bind mounted from a memory file system (usually "tmpfs") to /etc/machine-id during the early phase of the boot process. This may happen because /etc is initially read-only and was missing a valid machine ID file at that point.

This command will execute no operation if /etc/machine-id is not mounted from a memory file system, or if /etc is read-only. The command will write the current transient machine ID to disk and unmount the /etc/machine-id mount point in a race-free manner to ensure that this file is always valid and accessible for other processes.

This command is primarily used by the **systemd-machine-id-commit.service**(8) early boot service.

## --print

Print the machine ID generated or committed after the operation is complete.

## -h, --help

Print a short help text and exit.

#### --version

Print a short version string and exit.

## **EXIT STATUS**

On success, 0 is returned, a non-zero failure code otherwise.
