NAME

AnyEvent::Strict – force strict mode on for the whole process

SYNOPSIS

```
use AnyEvent::Strict;
# strict mode now switched on
```

DESCRIPTION

This module implements AnyEvent's strict mode.

Loading it makes AnyEvent check all arguments to AnyEvent-methods, at the expense of being slower (often the argument checking takes longer than the actual function). It also wraps all callbacks to check for modifications of $_, which indicates a programming bug inside the watcher callback.

Normally, you don't load this module yourself but instead use it indirectly via the PERL_ANYEVENT_STRICT environment variable (see AnyEvent). However, this module can be loaded manually at any time.
